Molecular Mechanisms of Dementia Wilma Wasco, Rudolph Tanzi, 1996-11-01 The past decade has witnessed a revolution in the attempts of scientists to understand the molecular basis of dementia Although dementia as defined by global cognitive decline involving gradual loss of memory reasoning judgment and orientation presents most commonly in the form of Alzheimer's disease AD an assortment of other less common disorders such as prion and Pick's disease can also lead to symptoms that are similar to those observed in patients with AD The primary goal of Molecular Mechanisms of Dementia is to address the various mechanisms and multifaceted approaches currently being employed to more clearly delineate the etiological and pathogenic events responsible for the onset of dementia Perhaps the greatest boon to obtaining a clearer understanding of the causes of AD has come from genetic and molecular biological studies carried out over the past decade At the genetic level it has become increasingly clear that AD is a heterogeneous disorder that can be broadly classified into two categories Late onset 60 yr cases which account for the vast majority of AD genetically involve susceptibility genes representing risk factors for the disease e.g inheritance of the $\epsilon 4$ allele of the Apolipoprotein E gene In many cases the susceptibility gene can act as a modifier that modulates the pathogenic cascade occurring subsequent to a separate etiological event initiating or causing the disorder
