Ting-Ting Hwang, Robert Michael Owens, Mary Jane Irwin, Fellow, IEEE, and Kwei-Hua Wang

Abstract—In this paper, we consider the problem of configuring Field Programmable Gate Arrays (FPGAs) so that some given function is computed by the device. Obtaining the information necessary to configure a FPGA entails both logic synthesis and logic unembedding. Due to the very constrained nature of the unembedding process, this problem differs from traditional hardware logic synthesis in that the structure (or lack thereof) of the synthesized logic is much more important. Furthermore, a matrix-like internal count is much less important. We present a communication complexity-based characterization technique that appears to be more suitable for FPGA synthesis than other embedded logic synthesis methods. The key is that our logic optimization technique based on reducing communication complexity is good enough to allow a simple technology mapping to work well for FPGA devices.

I. INTRODUCTION

FIELD PROGRAMMABLE GATE Arrays (FPGAs) are a recent technology that provides users programmability in hardware. Because of their very short turnaround time and low manufacturing cost, FPGAs have found an increasing number of systems prototyping using FPGAs. One important class is the RAM-based FPGA also called "look-up table FPGA's". A novel feature of these devices is that each basic block can implement any logic function that satisfies the EO constraints of the basic block. The communication between the basic blocks models a local expansion, defined by program controlled gate interconnects. From the above description, we also see that two features of FPGA's that the logic synthesis process has to take into consideration are 1) structure with independent wiring look up table (LUT) and 2) restricted interconnects. To configure a FPGA requires programming both the LUT and the interconnect. In this paper, considering a FPGA is similar to the traditional custom VLSI synthesis process. Given a logic function to be realized, an equivalent embedded logic description is first generated, the synthesized description is technology mapped, and finally, the mapped description is unembedded in circuitry.

However, even though similar in approach, traditional logic synthesis tools may not be well suited for FPGA configurations for the following two reasons. First, because each LUT can

simulate any k -input gate, where k is the input limit of a LUT function unit, it is possible for large expressions (other interpretations of the synthesized description) to be mapped to a single LUT if the expression has few unique literals, 3 or fewer different variables. For example, consider the case where basic block is a 16-bit, 4 input LUT and let $f_1 = abcd$ and $f_2 = abcd + cd + cd + cd + cd$. Although in terms of literal count f_2 is more complex than f_1 , f_2 can be realized using one 4-input LUT with a 3-input feed into 4-input LUT. This implies that traditional "logic synthesis" that focuses on unembedding the number of blocks may not be the best approach for FPGA's. The process of logic synthesis and technology mapping for FPGA's should not be decoupled. Second, because of the FPGA's structure, unembedding the mapped description requires less flexibility than in traditional custom VLSI synthesis. This implies that how well a mapped description can be embedded in a FPGA can be very dependent on the structure of the mapped description. To embed a global circuit graph is not to perform a mapping a simplified circuit graph to a device. All of this means that, how good the final configuration is will be much more dependent on the structure of the embedded description than in traditional VLSI synthesis.

We present a logic synthesis technique that overcomes these two limitations. Our technique is based on minimizing the communication complexity of the synthesized circuit rather than minimizing on literal count. The remainder of this paper is organized as follows. In Section II, we review the communication-based logic synthesis techniques that is used to construct a global technology-independent structure. In Section III, we show that communication-based logic synthesis is more suitable for configuring FPGAs. We then present an algorithm for mapping technology independent logic to FPGA's in Section IV. Some benchmarking results and conclusions are given in Section V.

II. COMMUNICATION COMPLEXITY-BASED LOGIC SYNTHESIS

In this section, we will give an overview of communication complexity based logic synthesis. A detailed description can be found in [11]. Roughly, communication complexity-based logic synthesis can be stated as follows: For some function

$$y = f(x) \quad f: 2^n \rightarrow 2^m \quad x \in \{1, \dots, 2^n\}$$

where the elements of x are the n binary inputs and the elements of y are the m binary outputs of the function and some partitioning (x_1, x_2) of x , let I_1 , I_2 and J_1 be a set of

Ling,2009 As Field Programmable Gate Array FPGA capacity can now support several processors on a single device the scalability of FPGA design tools and methods has emerged as a major obstacle for the wider use of FPGAs For example logic synthesis which has traditionally been the fastest step in the FPGA Computer Aided Design CAD flow now takes several hours to complete in a typical FPGA compile In this work we address this problem by focusing on two areas First we revisit FPGA logic synthesis and attempt to improve its scalability Specifically we look at a binary decision diagram BDD based logic synthesis flow referred to as FBDD where we improve its runtime by several fold with a marginal impact to the resulting circuit area We do so by speeding up the classical cut generation problem by an order of magnitude which enables its application directly at the logic synthesis level Following this we introduce a guided partitioning technique using a fast global budgeting formulation

which enables us to optimize individual pockets within the circuit without degrading the overall circuit performance By using partitioning we can significantly reduce the solution space of the logic synthesis problem and furthermore open up the possibility of parallelizing the logic synthesis step The second area we look at is the area of Engineering Change Orders ECOs ECOs are incremental modifications to a design late in the design flow This is beneficial since it is minimally disruptive to the existing circuit which preserves much of the engineering effort invested previously in the design In a design flow where most of the steps are fully automated ECOs still remain largely a manual process This can often tie up a designer for weeks leading to missed project deadlines which is very detrimental to products whose life cycle can span only a few months As a solution to this we show how we can leverage existing logic synthesis techniques to automatically modify a circuit in a minimally disruptive manner This can significantly reduce the turn around time when applying ECOs
