## SUMMARY

Load management (LM) is supposed to have a vital role in future energy management systems. This article presents an overview and comparison of LM techniques along with related technologies and implementation challenges in smart grid. The article also covers consumer and utility concerns in context of LM to enhance readers' intuition about the topic. Two major categories of LM techniques, incentive-based and dynamic pricing-based schemes, have been discussed and compared. Most commonly used incentive-based direct load control is elaborated in detail. Dynamic pricing-based energy consumption scheduling schemes, featuring peak load reduction and consumers' energy cost minimization at residential level, are also emphasized. Furthermore, the article includes a description of dynamic pricing-based home energy management and associated optimization techniques as well as comparison of the latest schemes. ## 1. INTRODUCTION

Energy is one of the most important components of human life that is present ubiquitously and can be rendered as soul of modern machine age. Energy management is an important and interesting focus of research since decades. According to the International Energy Agency, the total primary energy supply of the world has been increased to 13 113 million tons of oil equivalent in 2011 as compared with 6109 million tons of oil equivalent in 1973 [1]. The largest amount of energy is consumed in buildings, which is estimated almost 40% of the world total consumption and has been doubled in 2010 as compared with 1971 [2]. It is the use of energy by the occupants of the buildings that is usually expressed as per capita energy consumption and taken as an index for development and prosperity of a country [3].

Electricity is distributed through existing electro-mechanical grid, which has been serving since the 19th century. Generation of more power to meet ever-increasing demand, which is expected to be doubled by 2020 [4], has many concerns regarding the limited fossil fuels and high carbon emissions. Carbon emissions deteriorate our environment and put a question mark over global sustainability.

Renewable energy resources are a cleaner form of energy; however, the energy density and technological maturity of the fossil fuels still dominate their use. It is

estimated that the US energy profile will constitute 33% of renewable resources by 2020 with high penetration of wind and solar power plants [5]. Integration of the huge amount of distributed generation, usually consisting of renewable resources, to the power grid has raised many issues [6]. The concept of virtual utility to integrate different kinds of distributed generation to a central energy (heat and electricity) network has been proposed in [7]. Unpredictable behavior of these intermittent energy sources has adverse effects on power system stability.

In the beginning, LM procedures were based on unidirectional communication between users and utilities [8]. These procedures were mainly implemented by the utilities, and the role of users in LM programs was negligible. However, integration of advanced communication infrastructure enables bi-directional flow of data and power among different stakeholders of power system and hence allows more efficient LM involving both utility and consumers [9].

The need to control the demand in order to shape the load profile was first realized in the 1970s [10]. Now, it has evolved to the concept of demand side management (DSM) and is characterized by utility operations and incentives for the consumers in order to bring power usage at desired level at all times. Major objectives of DSM include peak clipping, valley filling, peak shifting, and deploying new efficient uses [11]. DSM can help the consumers to
