ABSTRACT

The prostate gland is a solid one-lobed and median organ situated in the male pelvis, under the bladder. Prostatic carcinoma (PCa) is frequently located in the peripheral portion of the gland, so that preoperative imaging suits from radiological assessment. However, the role of multiparametric magnetic resonance imaging is now critical, to guide prostate biopsy. The indications for robot-assisted radical prostatectomy (RRP) in PCa treatment are essentially the same as those for open and laparoscopic RP. The robot allows the surgeon to have better, less-invasive control of the tissue, increased by 3D vision, working through small incisions incisions. Our previous experimental experience had led us to maintain this approach in RRP. Critical urotheloscopic operations during robotic surgery included a steep Trendelenburg position, constant access to the patient, and the effects of CO₂ insufflation, as a consequence, not every patient can benefit from RRP. Beyond the introduction of robotic surgery the improved knowledge of preoperative neurovascular structures has permitted the identification of new operative anatomical landmarks and surgical planes between prostate and neurovascular bundles during nerve-sparing procedures, in the continuous attempt to reduce the detrimental effects on sexual function and urinary continence.
