

Optical interferometry

- Optical interferometry has been used for axial length and other intraocular measurements since the introduction of **IOL master** (2000)
- Interferometry splits a single incoming beam of coherent light into two identical beams with a partially reflecting mirrors . Each of these beams travels along a different path , and are recombined before arriving the detector . The difference in the distance traveled by each beam creates a phase difference between them.
- The phase difference creates an interference pattern that is diagnostic of a physical change in the path length itself or a change in the refractive index along the path .
- Optical biometry uses a 780um infrared light wave that has 8x the resolution of a 10MHZ soundwave , making the measurement of axial length very precise and avoiding operator variations.
