

MOLECULAR MEDICINE NOTES

WEEK 1 – CANCER GENETICS 01

LECTURE (slide 1, video 1-3)

- Cancer cells – can often be distinguished from normal cells by microscopic examination. They are usually less well differentiated than normal cell or benign tumour cells. The presence of invading cells in an otherwise normal tissue section is used to diagnose a malignancy.
- Stem cells – are housed in the base of the crypts. Stem cells give rise to the transit-amplifying compartment where most cell production occurs.

- Multi Step Tumorigenesis –
 - The formation of a tumour is a complex process that usually proceeds over a period of decades.
 - Normal cells evolve into cells with increasingly neoplastic phenotypes through a process termed tumour progression.
 - Rarely does it proceed far enough at any single site to make us aware of a clinically detectable tumour mass.
- Tumour progression – is driven by a sequence of randomly occurring mutations and epigenetic alterations of DNA that affect.
- The genes controlling cell proliferation and survival – Other traits associated with the malignant cell phenotype. Most human cancers develop over many decades of time.
- Epidemiologic studies – have shown that age is a surprisingly large factor in the incidence of cancer. The risk of dying from colon cancer is as much as 1000 times greater in a 70 year old man than in a 10 year old boy.
- The incidence of lung cancers –
 - Cigarette smoking was relatively uncommon until World War II, when large numbers of men acquired the habit.
 - Encouraged by cigarettes they received in their rations.
