

about the mother's glucose control as well as any maternal illnesses. Congenital myotonic dystrophy is an inherited condition that can be difficult to diagnose in a mother who is asymptomatic; yet a significant percentage of future pregnancies carry a 50 percent risk of being affected by it.

Causes of death differ in fetuses that have become macerated (e.g., not delivered for sometime after fetal death has occurred) and those that are freshly expelled. Macerated fetuses have a significantly higher chance of having been aborted because of chromosomal abnormality, a placental problem, or multiple malformations. Fresh fetuses are more likely to have died of nonrecurrent causes, such as cord accidents or infection. Chromosome studies need to be performed in fetuses when the mother has had recurrent losses. Such studies should also be done in any fetus with ultrasound-detected or obvious external abnormalities and in fetuses with hydrops, growth retardation, or maceration.

In a study of 500 cases of pregnancy loss, a cause could be established in 90 percent of intact and 30 percent of nonintact fetuses. Chromosomal abnormalities accounted for 19 percent; placental abnormalities, 11 percent; infections, 7 percent; cord abnormalities, 6 percent; neural tube defects, 8 percent; renal, central nervous system, or cardiac abnormalities, 6 percent; twins, 5 percent; recognizable syndromes, 4 percent; skeletal deformities, 2 percent; and other causes, 11 percent. Of particular significance was the finding of maternal immune rejection (possibly preventable) in about 10 percent of the losses. Certain placental pathologies were typical of this condition and underscore the importance of examining the placenta in cases of fetal loss. The fetal findings in maternal "immune rejection" included growth retardation and hydrops. Most of the women also had a history of recurrent miscarriages.

Many fetal conditions are yielding to advanced diagnostic and therapeutic modalities. The role of the placenta in fetal loss offers a major new direction for exploration. Families want and deserve answers as to why a miscarriage happened and what can be done to prevent its happening again. The best way to provide such answers is to know more about the precise mechanisms of fetal loss.

OPEN DISCUSSION PERIOD

A participant asked whether altered islet-cell function in the children in the diabetes study involved permanent down-regulation of insulin receptors. The question cannot be answered at present. Insulin sensitivity and beta-cell function continue to be measured in the children who show impaired glucose tolerance, and comparative information is being sought through animal studies.

Another participant asked what is known about the receptor for placental lactogen and where it is distributed in the fetus. Studies of sheep fetuses show the presence of hPL as early as six weeks into gestation, binding to cells in the liver, ovary, testis, and adrenal gland. In mice there is also a high degree of
