Contributions to linear discriminant analysis with applications to growth curves Edward Kanuti Ngailo, 2020-05-06 This thesis concerns contributions to linear discriminant analysis with applications to growth curves Firstly we present the linear discriminant function coefficients in a stochastic representation using random variables from the standard univariate distributions We apply the characterized distribution in the classification function to approximate the classification error rate The results are then extended to large dimension asymptotics under assumption that the dimension p of the parameter space increases together with the sample size n to infinity such that the ratio converges to a positive constant $c \in (0, 1)$ Secondly the thesis treats repeated measures data which correspond to multiple measurements that are taken on the same subject at different time points We develop a linear classification function to classify an individual into one out of two populations on the basis of the repeated measures data that when the means follow a growth curve structure The growth curve structure we first consider assumes that all treatments groups follows the same growth profile However this is not necessarily true in general and the problem is extended to linear

classification where the means follow an extended growth curve structure i.e. the treatments under the experimental design follow different growth profiles. At last a function of the inverse Wishart matrix and a normal distribution finds its application in portfolio theory where the vector of optimal portfolio weights is proportional to the product of the inverse sample covariance matrix and a sample mean vector. Analytical expressions for higher order moments and non central moments of the portfolio weights are derived when the returns are assumed to be independently multivariate normally distributed. Moreover the expressions for the mean variance skewness and kurtosis of specific estimated weights are obtained. The results are complemented using a Monte Carlo simulation study where data from the multivariate normal and t distributions are discussed. Den här avhandlingen studerar diskriminantanalys klassificering av tillväxtkurvor och portföljteori. Diskriminantanalys och klassificering är flerdimensionella tekniker som används för att separera olika mängder av objekt och för att tilldela nya objekt till redan definierade grupper så kallade klasser. En klassisk metod är att använda Fishers linjära diskriminantfunktion och när alla parametrar är kända så kan man enkelt beräkna sannolikheterna för felklassificering. Tyvärr är så sällan fallet utan parametrarna måste skattas från data och då blir Fishers linjära diskriminantfunktion en funktion av en Wishartmatris och multivariat normalfördelade vektorer. I den här avhandlingen studerar vi hur man kan approximativt beräkna sannolikheten för felklassificering under antagandet att dimensionen på parameterutrymmet är tillsammans med antalet observationer genom att använda en så kallad stokastisk representation av diskriminantfunktionen. Upprepade mätningar av samma individ eller objekt går att modellera med så kallade tillväxtkurvor. Vid klassificering av tillväxtkurvor eller rättare sagt av upprepade mätningar för en ny individ bör man ta tillvara på både den spatiala och temporal informationen som finns hos dessa observationer. Vi vidareutvecklar Fishers linjära diskriminantfunktion att passa för upprepade mätningar och beräknar asymptotiska sannolikheter för felklassificering. Till sist kan man notera att snarlika funktioner av Wishartmatriser och multivariat normalfördelade vektorer dyker upp när man vill beräkna de optimala vikterna i portföljteori. Genom en stokastisk representation studerar vi egenskaperna hos portföljvikterna och gör dessutom en simuleringsstudie för att först vad som händer när antagandet om normalfördelning inte är uppfyllt.
