Exploratory Vision The Active Eye:

Exploratory Vision Michael S. Landy, Laurence T. Maloney, Misha Pavel, 2012-12-06 Advances in sensing signal processing and computer technology during the past half century have stimulated numerous attempts to design general purpose machines that see. These attempts have met with at best modest success and more typically outright failure. The difficulties encountered in building working computer vision systems based on state of the art techniques came as a surprise. Perhaps the most frustrating aspect of the problem is that machine vision systems cannot deal with numerous visual tasks that humans perform rapidly and effortlessly. In reaction to this perceived discrepancy in performance various researchers notably Marr 1982 suggested that the design of machine vision systems should be based on principles drawn from the study of biological systems. This neuro-morphic or anthropomorphic approach has proven fruitful. The use of pyramid multi-resolution image representation methods in image compression is one example of a successful application based on principles primarily derived from the study of biological vision systems. It is still the case however that the performance of computer vision systems falls far short of that of the natural systems since they are intended to mimic suggesting that it is time to look even more closely at the remaining differences between artificial and biological vision systems. *Learning-Based Robot Vision* Josef Pauli, 2003-06-29 Industrial robots carry out simple tasks in customized environments for which it is typical that nearly all effector movements can be planned during an offline phase. A continual control based on sensory feedback is at most necessary at effector positions near target locations utilizing torque or haptic sensors. It is desirable to develop new generation robots showing higher degrees of autonomy for solving high level deliberate tasks in natural and dynamic environments. Obviously camera equipped robot systems which take and process images and make use of the visual data can solve more sophisticated robotic tasks. The development of a semi-autonomous camera equipped robot must be grounded on an infrastructure based on which the system can acquire and/or adapt task-relevant competences autonomously. This infrastructure consists of technical equipment to support the presentation of real world training samples, various learning mechanisms for automatically acquiring function approximations and testing methods for evaluating the quality of the learned functions. Accordingly to develop autonomous camera equipped robot systems one must first demonstrate relevant objects, critical situations and purposive situation-action pairs in an experimental phase prior to the application phase. Secondly the learning mechanisms are responsible for acquiring image operators and mechanisms of visual feedback control based on supervised experiences in the task-relevant real environment. This paradigm of learning-based development leads to the concepts of compatibilities and manifolds. Compatibilities are general constraints on the process of image formation which hold more or less under task-relevant or accidental variations of the imaging conditions. *The Eyes Have It: An Exploration of the Human Visual System* Pasquale De Marco, 2025-07-15 Embark on a captivating journey into the realm of human vision with *The Eyes Have It: An Exploration of the Human Visual System*.
