

BERKELEY'S CORTINARIUS

Cortinarius berkeleyi

A cortina, as has been mentioned, is a temporary veil that soon is torn to the margin of the cap. This hides the gills in young mushrooms. Later the veil breaks, leaving only a very slight trace on the stem. It is sometimes very difficult to identify the species from the traces left by the veil, which are almost invisible. For this reason it is better to rely on other characteristics, especially the color of the spores.

Cap Fleecy, convex, then flattened, slightly wrinkled at rim when wet. Coppery-brown with a hint of pink. Striated margin.

Gills Adnate, emarginate, unequal, flat turning fringed.

Stem Rust-colored.

Spores White with pale lilac streaks, thick with bulbous base joined to the cap by a cortina when young (hence its name). The veil tears when the mushroom expands and sometimes leaves no trace on the stem as it grows.

Habitat Woods.

Season Summer, fall.

Notes All the Cortinari are edible except one, which is quite as dangerous as Amanita phalloides and for that reason we should get to know it. The Mountain or Golden Cortinarius (*Cortinarius praecox*).
